# UTILITY PATENT APPLICATION TRANSMITTAL

(Only for new nonprovisional applications under 37 C.F.R. § 1.53(b))

Attorney Docket No. **Bancal-8**  
First Inventor or Application Identifier **Bancal**  
Title **Flat Display Screen Resistive Anode**  
Express Mail Label No. **EJ596854523**

**APPLICATION ELEMENTS**  
See MPEP chapter 600 concerning utility patent application contents.

**ADDRESS TO:**  
Assistant Commissioner for Patents  
Box Patent Application  
Washington, DC 20231

- ☒ \* Fee Transmittal Form (e.g., PTO/SB/17)  
(Submit an original and a duplicate for fee processing)
- ☒ Specification [Total Pages **16**]  
(preferred arrangement set forth below)
  - Descriptive title of the invention
  - Cross References to Related Applications
  - Statement Regarding Fed sponsored R & D
  - Reference to Microfiche Appendix
  - Background of the Invention
  - Brief Summary of the Invention
  - Brief Description of the Drawings (if filed)
  - Detailed Description
  - Claim(s)
  - Abstract of the Disclosure
- ☒ Drawing(s) (35 U.S.C. 113) [Total Sheets **2**]
- Oath or Declaration [Total Pages **3**]
  - ☐ Newly executed (original or copy)
  - ☐ Copy from a prior application (37 C.F.R. § 1.63(d))  
(for continuation/divisional with Box 16 completed)
    - ☐ DELETION OF INVENTOR(S)  
Signed statement attached deleting inventor(s) named in the prior application, see 37 C.F.R. §§ 1.63(d)(2) and 1.33(b).

- ☐ Microfiche Computer Program (Appendix)
- Nucleotide and/or Amino Acid Sequence Submission (if applicable, all necessary)
  - ☐ Computer Readable Copy
  - ☐ Paper Copy (identical to computer copy)
  - ☐ Statement verifying identity of above copies

## ACCOMPANYING APPLICATION PARTS

- ☐ Assignment Papers (cover sheet & document(s))
- ☐ 37 C.F.R. § 3.73(b) Statement of Power of Attorney (when there is an assignee)
- ☐ English Translation Document (if applicable)
- ☒ Information Disclosure Statement (IDS)/PTO-1449 ☒ Copies of IDS Citations
- ☒ Preliminary Amendment
- ☒ Return Receipt Postcard (MPEP 503) (Should be specifically itemized)
- ☐ Small Entity Statement(s) ☐ Statement filed in prior application, (PTO/SS99-12) Status still proper and desired
- ☒ Certified Copy of Priority Document(s) (if foreign priority is claimed)
- ☐ Other:

\*NOTE FOR ITEMS 1 & 13: IN ORDER TO BE ENTITLED TO PAY SMALL ENTITY FEES, A SMALL ENTITY STATEMENT IS REQUIRED (37 C.F.R. § 1.27), EXCEPT IF ONE FILED IN A PRIOR APPLICATION IS RELIED UPON (37 C.F.R. § 1.28)

16. If a CONTINUING APPLICATION, check appropriate box, and supply the requisite information below and in a preliminary amendment:

☐ Continuation ☐ Divisional ☐ Continuation-in-part (CIP) of prior application No. \_\_\_\_\_  
Prior application information: Examiner \_\_\_\_\_ Group / Art Unit: \_\_\_\_\_  
For CONTINUATION or DIVISIONAL APPS only: The entire disclosure of the prior application, from which an oath or declaration is supplied under Box 4b, is considered a part of the disclosure of the accompanying continuation or divisional application and is hereby incorporated by reference. The incorporation can only be relied upon when a portion has been inadvertently omitted from the submitted application parts.

## PRELIMINARY AMENDMENT

Dear Sir:

Preliminary to the first Official Action in the above-captioned application, please amend the same as follows:

## IN THE CLAIMS

Please amend the following claims:

6.(AMENDED) The anode of [any of claims 1 to 5] claim 1, wherein the resistive layer (8, 8', 8'') is not patterned.

7.(AMENDED) The anode of [any of claims 3 to 5] claim 3, wherein the resistive layer (8'') has the same pattern as the reflective layer (10).

8.(AMENDED) The anode of [any of claims 1 to 7] claim 1, wherein the resistive layer (8) has, at least in the active screen area, the same pattern as the biasing conductive layer (5).

9.(AMENDED) The anode of [any of claims 1 to 8] claim 1, wherein said conductive layer has a pattern of alternate strips (5R, 5G, 5B) interconnected in at least two sets.

Please cancel claim 10.

Please add the following claim:

11.(NEW) A flat display screen including:

a cathodoluminescent anode (2) having phosphor elements (4R, 4G, 4B, 4'R, 4'G, 4'B) intended for being excited by an electron bombardment, these elements being deposited on at least one biasing electrode including, at least under the phosphor elements, a resistive layer (8, 8', 8'') deposited on a conductive layer (5B, 5R, 5G) for biasing the phosphor elements; and

a cathode (1) for generating electrons bombarding the anode.

### STATUS OF THE CLAIMS

Claims 1-10 are pending. Claims 6-9 has been amended herein, claim 10 has been cancelled herein, and claim 11 has been added herein.

### REMARKS

Claims 6, 8, and 9 each have been amended to depend only from claim 1, and claim 7 has been amended to depend only from claim 3 only. Claim 10 has been cancelled and rewritten as

new claim 11 in order to comply with U.S. practice.

No fees are believed due as a result of this Preliminary Amendment. The Commissioner is hereby authorized to charge any other fees which may be required, or credit any overpayment, to Deposit Account number 50-1057.

Respectfully submitted,

Paul A. Schwarz, Esq.

## FLAT DISPLAY SCREEN RESISTIVE ANODE

### BACKGROUND OF THE INVENTION

#### Field of the Invention

The present invention relates to a flat display screen anode having phosphors excited by electrons, for example, of microtip type. It more specifically relates to the biasing of phosphor elements of an anode provided with phosphor elements of different colors biased per color, for example, alternate strips  
5 of phosphor elements organized in combs.

#### Discussion of the Related Art

Fig. 1 very schematically shows the structure of a flat microtip screen of the type to which the present invention relates. This screen is comprised of two plates. A first plate 1,  
10 currently called the cathode plate, is arranged to face a second plate 2, currently called the anode plate. The two plates are spaced apart from each other by spacers 3 regularly distributed in the screen surface, and a vacuum is created in the area defined by the two plates and a peripheral sealing joint 4.

15 Cathode plate 1 includes electron generation elements and pixel selection elements (not shown) that may be organized in different ways, for example, as described in US patent n° 4,940,916 of the Commissariat à l'Energie Atomique in the case of microtip screens. Anode plate 2 is, in the case of a color

screen, provided with alternate strips of phosphor elements, each strip corresponding to a color (red, green, blue).

Figs. 2A and 2B very schematically show a front view and a cross-section view of a portion of an anode plate. In Fig. 2B, the surface corresponding to the internal screen surface faces up. The anode includes, for example, alternate strips 4R, 4G, 4B of respectively red, green, blue phosphor elements. As illustrated in Fig. 2B, the strips of phosphor elements are arranged on corresponding conductive strips 5R, 5G, 5B generally organized in combs, all strips 5R being interconnected, as well as all strips 5G and all strips 5B. In certain cases, the phosphor elements are distributed in elementary patterns, each of which generally corresponds to a pixel (in fact, a sub-pixel of each color for a trichromatic screen). The "pixelized" phosphor elements can then still be addressed by biasing electrodes in conductive strips (5G, 5B and 5R) such as described in relation with Figs. 2A and 2B, but a specific mask is used to deposit the phosphor elements.

Two great categories of flat screens can be distinguished according to whether the user looks at the screen from the anode side or from the cathode side. In the first case, the light emitted by the phosphor elements propagates through the anode plate (downwards in Fig. 2B). The material of conductive strips 5R, 5G, 5B then is transparent, currently indium and tin oxide (ITO). In the second case, transparent electrodes 5R, 5B, 5G are replaced with opaque and preferably reflective electrodes, so that the largest possible part of the light emitted by phosphor elements 4R, 4G, 4B is sent back to the cathode once the phosphors have been excited by an electron bombardment. Electron generating plate 1 then is at least partially transparent and the observation is performed through this cathode plate.

In a color screen (or in a monochrome screen formed of two alternate sets of strips of phosphor elements of same color), the sets of strips (for example, blue, red, green) are often alternately positively biased with respect to cathode 1, so that

the electrons extracted from the emissive elements (for example, the microtips) of a pixel of the cathode are alternately directed towards phosphor elements 4R, 4G, 4B facing each of the colors.

The selection control of the phosphor that is to be  
 5   bombarded by the electrons imposes controlling, respectively, the  
 biasing of the phosphor elements of the anode, color by color.  
 Generally, the strips 5R, 5G, 5B supporting phosphor elements to  
 be excited are biased under a voltage of several hundreds of  
 volts with respect to the cathode, the other strips being at a  
 10   zero potential. The choice of the values of the biasing poten-  
 tials is linked to the characteristics of the phosphor elements  
 and of the emissive means.

In some cases, the anode may, while being formed of  
 several sets of phosphor elements or the like, not be switched by  
 15   sets of strips. All strips are then biased to a same potential,  
 at least for the duration of a display frame. The anode is then  
 said to be unswitched.

The potential difference between the anode and the  
 cathode is essentially due to the inter-electrode distance, that  
 is, to the thickness of the internal space. A maximum potential  
 20   difference is desired for reasons of display brightness, which  
 results in searching the greatest possible inter-electrode  
 distance. However, the structure of the inter-electrode space,  
 that includes spacers 3 likely to create dark areas in the screen  
 25   if their size is too large, prevents from increasing this inter-  
 electrode distance.

The necessary trade off leads to choosing an anode-  
 cathode voltage value that is critical from the point of view of  
 electric arc formation. Destructive electric arcs can then be  
 30   caused by the smallest dimensional irregularity of the distance  
 separating an emissive means of the cathode from the phosphor  
 elements of the anode. Such irregularities are, moreover, inevi-  
 table given the small dimensions and the techniques used to form  
 the anode and the cathode.

On the cathode side, a resistive layer is provided in the case of microtip screens to receive the microtips and thus limit the formation of destructive short-circuits between the microtips and a control grid associated with the cathode.

5       Conversely, on the anode side, arcs may occur not only between the cathode plate and those of the anode phosphor elements that are biased to attract electrons emitted by the microtips, but also between two neighboring strips of phosphor elements, due to the potential difference between the two strips.

10       In the case of a monochrome screen where the anode is formed of a conductive plane supporting phosphor elements of same color or in the case of an anode (color or monochrome) with several unswitched strips, the risk of arcs only exists between the anode and the cathode.

15       To limit the occurrence of such lateral arcs, it is currently provided to arrange, between anode strips 5B, 5R, 5G, interstitial strips 7 made of an insulating material (generally silicon oxide).

20       However, in practice, the efficiency of such insulating strips is limited for several reasons.

First, these strips are inoperative with respect to the forming of electric arcs between the anode and the cathode.

Further, and although this does not necessarily appear in Figs. 2A and 2B in which the scales have not been respected,

25       phosphor elements 4R, 4G, 4B significantly extend beyond the interstitial strips. Indeed, the thickness of the strips of phosphor elements is generally on the order of some ten  $\mu\text{m}$  and the forming of silicon oxide insulating strips of such a thickness is, in practice, incompatible with the technologies

30       used for manufacturing the anodes, so that the thickness of strips 7 generally is on the order of 1 to 2  $\mu\text{m}$ , their width being on the order of 10 to 20  $\mu\text{m}$ .

Further, during the deposition of the phosphor elements through a deposition mask, a slight misalignment of the mask may

35       occur, so that a portion of conductive strips 5R, 5G, 5B or of

the insulated areas becomes accessible once the screen is completed and thus favors the forming of arcs.

A first known solution to attempt to reduce the forming of arcs between the anode and the cathode is to provide, at the  
5 end of each conductive strip 5R, 5G, 5B, a resistor between the power supply line and the strip. As soon as a strong current appears in the strip, the resistor causes a voltage drop. As a result, the potential difference between the conductive strip and the cathode decreases and has the overvoltage generating the arc  
10 disappear.

A disadvantage of such a solution is that it does not protect from the forming of a lateral electric arc, that is, an arc between two neighboring strips 5R, 5G, 5B. A local current circulation may indeed occur between two strips, which is then  
15 not prevented by the end resistors.

Another disadvantage of using such resistors in series with the strips is that the resistors are generally made of ruthenium, the resistivity of which is stabilized by anneal. This anneal at high temperature (on the order of 600°C) necessary to  
20 stabilize the resistor raises problems of compatibility with the screen manufacturing process that requires, for the case where the conductive strips are made of aluminum in the case of a transparent anode, temperatures under 600°C. Further, such a manufacturing method by anneal is difficult to control.

Another disadvantage of series resistors interposed between the anode conductive strips is that they form heating areas for the anode conductive tracks at the screen periphery.

A second known solution is described in French patent application n° 2,732,160. This solution consists of depositing  
30 the strips of phosphor elements on strongly resistive strips and bringing the biasing necessary to the phosphors by lateral biasing strips on either side of each resistive strip.

Even though this solution can provide satisfactory results, it requires a significant space between each strip of  
35 phosphor elements to house therein two biasing conductors

respectively associated with two neighboring strips while sufficiently separating these biasing conductors from each other to maintain a necessary lateral insulation between them. Thus, this solution is, in practice, more particularly intended for  
 5 screens of low resolution.

Conversely and as an example, for an anode plate in which the surface of each pixel is a square having a side of approximately 300  $\mu\text{m}$ , the anode strips each have a neighboring width, but under 100  $\mu\text{m}$ , and insulating strips 7 have a width on  
 10 the order of some ten  $\mu\text{m}$ . In such a case, the implementation of a solution of local protection by a resistive layer laterally surrounded by biasing strips cannot be envisaged due to the small distance between anode strips.

#### Summary of the invention

The present invention aims at overcoming the disadvantages of conventional techniques by providing a flat display  
 15 screen anode that suppresses the risk of occurrence of an electric arc between the anode and the cathode plate, or between two neighboring strips of phosphor elements of the anode, without adversely affecting the screen brightness.

The present invention also aims at providing a solution  
 20 that is compatible with conventional distances between two strips of phosphor elements.

The present invention also aims at providing a solution that is particularly adapted to a "transparent" cathode screen,  
 25 that is, the cathode plate of which forms the screen display surface.

The present invention further aims at providing a solution that respects conventional anode manufacturing methods and, in particular, the masks used in this manufacturing.

To achieve these objects, the present invention provides a flat display screen anode, including phosphor elements  
 30 intended for being excited by an electron bombardment, these elements being deposited on at least one biasing electrode including, at least under the phosphor elements, a resistive

layer deposited on a conductive layer for biasing the phosphor elements.

According to an embodiment of the present invention, the phosphor elements are directly deposited on the resistive layer.

According to an embodiment of the present invention, the phosphor elements are deposited on a reflective conductive layer, itself deposited on the resistive layer.

According to an embodiment of the present invention, the reflective layer is deposited according to elementary patterns of small dimension in the anode surface.

According to an embodiment of the present invention, the phosphor elements are deposited according to the elementary pattern of deposition of the reflective layer.

According to an embodiment of the present invention, the resistive layer is not patterned.

According to an embodiment of the present invention, the resistive layer has the same pattern as the reflective layer.

According to an embodiment of the present invention, the resistive layer has, at least in the active screen area, the same pattern as the biasing conductive layer.

According to an embodiment of the present invention, said conductive layer has a pattern of alternate strips interconnected in at least two sets.

The present invention also provides a flat display screen including a cathode generating electrons bombarding a cathodoluminescent anode as mentioned above.

The foregoing objects, features and advantages of the present invention will be discussed in detail in the following non-limiting description of specific embodiments, in conjunction with the accompanying drawings.

#### **Brief Description of the Drawings**

Figs. 1, 2A and 2B, previously described, are meant to show the state of the art and the problem to solve;

Fig. 3 is a simplified partial cross-section view of a first embodiment of a flat display screen anode plate according to the present invention;

5 Figs. 4A and 4B very schematically and partially show, respectively in front view and in cross-section, a second embodiment of a flat screen anode according to the present invention more specifically intended for a screen having its surface formed by the cathode; and

10 Figs. 5A and 5B very schematically and partially show, respectively in front view and in cross-section, an alternative of the second embodiment of the present invention.

### Detailed Description

The same elements have been referred to with the same references in the different drawings. For clarity, only those elements necessary to the understanding of the present invention  
15 have been shown in the drawings and will be described hereafter. In particular, the structure of the cathode plate of a screen to which the present invention applies has not been detailed and is no an object of the present invention.

Fig. 3 shows a simplified cross-section view of a flat  
20 display screen anode according to a first embodiment of the invention. This anode includes, as previously, a supporting plate 2, for example a glass plate. In the case of a screen observable from the anode, the plate is of course transparent.

Anode conductive strips 5R, 5G, 5B are deposited, for  
25 example conventionally as illustrated in Figs. 2A and 2B, and are interconnected by sets of strips assigned to a same color.

A feature of the invention is that strips 5R, 5G, 5B, are covered with strips of a resistive material 8. According to the first embodiment of the present invention, strips of phosphor  
30 elements 4R, 4G, 4B are then deposited on resistive strips 8 and no longer, as in conventional screens, directly on conductive strips 5. Thus, the biasing electrodes of the phosphor elements comprise a conductive layer (in which are defined strips 5R, 5G, 5B) and a resistive layer 8.

A significant advantage of the present invention is that it conforms with the conventional anode manufacturing method. Indeed, resistive layer 8 can, in the first embodiment, be deposited, at least in the active portion of the screen, that  
 5 is, outside areas of interconnection of the strip sets, with the same pattern as anode conductive layers 5R, 5G, 5B, and thus by means of a same mask.

Another significant advantage of the present invention is that, while efficiently protecting the screen against destructive electric arcs, the present invention requires no increase of the lateral space between the strips of phosphor elements. The present invention thus is particularly well adapted to anodes of fine resolution.  
 10

Conventionally, anode strips 5R, 5G and 5B are preferably laterally separated by insulating interstitial strips 7.  
 15

It should be noted that the present invention enables protection against destructive electric arcs not only between the anode plate and the cathode plate, but also between neighboring strips of phosphor elements biased to different potentials. This  
 20 lateral protection is particularly efficient since it acts against any current flow, even local.

Further, in case of an incidental misalignment of the etch masks used to deposit phosphor elements 4R, 4G, 4B with respect to the mask for forming anode conductive strips 5R, 5G, 5B, the material now accessible is the material of resistive  
 25 layer 8, which prevents the forming of destructive electric arcs.

The choice of the material constitutive of resistive strips 8 depends on the application and, in particular, on the need for transparency (transparent anode) or for reflectiveness  
 30 (transparent cathode) of the resistive strips.

As an example of choice of material to form resistive strips 8, tin oxide, or thin silicon, deposited with a thickness preferably ranging between one and two  $\mu\text{m}$  may be used. Conductive anode strips 5R, 5G, 5B are, for example, made of ITO (transpar-

ent) or aluminum (reflective) with a thickness on the order of one tenth of a  $\mu\text{m}$ .

It should be noted that the invention provides a significant improvement with respect to series ruthenium resistors that must have a thickness of several tens of  $\mu\text{m}$ .

Further, the first embodiment of the invention also applies to the case of a monochrome screen in which the anode is formed of a plane of phosphor elements of same color or to the case of a screen (color or monochrome) in which the anode is formed of several unswitched sets of strips. In this case, resistive layer 8 is, preferably, deposited over the entire anode conductive layer.

Although the anode according to the invention has been described in relation with a trichromatic structure with elongated anode strips parallel to one another in the first embodiment, the structure of the anode phosphor elements may be very different. For example, it may be a structure of elementary patterns, each of which corresponds to one pixel. In such a case, the present invention provides the additional advantage of being implementable while a lateral protection solution would take too much space.

Figs. 4A and 4B show, respectively in front view and in cross-section, a second embodiment of a flat screen anode according to the present invention. This embodiment is more specifically intended for an anode having to reflect the light towards the cathode plate (1, Fig. 1) that forms the screen surface.

A feature of the second embodiment of the invention is that the biasing electrodes of the phosphor elements are here formed of an arrangement of three layers. As in the first embodiment, a biasing conductive layer 5 and a resistive layer 8 are present. However, according to this second embodiment, an additional conductive layer 10 is deposited on the resistive layer. A feature of this additional layer 10 is to be reflective to reflect light towards the cathode. Thus, conversely to the first embodiment that, when implemented in a transparent cathode

screen, provides a reflective resistive layer, the second embodiment enables using a resistive layer having any optical properties (transparent, absorbing or reflective), the reflection towards the cathode being ensured by the additional conductive layer 10.

It should be noted that the second embodiment of the invention more specifically applies to the case where the phosphor elements are deposited in elementary patterns by means of a specific mask including openings, for example, corresponding to the respective sizes of the screen pixels or of the sub-pixels of each screen color. This feature is linked to the presence of conductive layer 10 that must itself be deposited according to the elementary patterns to avoid a charge propagation along the electrode strips.

Thus, as illustrated in Fig. 4A, phosphor elements 4'B, 4'R and 4'G are deposited according to elementary patterns (in this example, rectangular) having small surface areas. It should however be noted that, in the embodiment illustrated by Figs. 4A and 4B, the distribution of the colors of the phosphor elements is always performed along strips above the conductive biasing strips 5B, 5R, and 5G that are formed according to an alternated strip pattern.

According to this embodiment of the invention, the additional reflective conductive layer is deposited by means of the same mask as the phosphor elements and is thus formed of areas of elementary patterns 10 under the phosphor elements. An insulating layer 7 is optionally provided between the anode strips. Layer 7 is deposited, as in the first embodiment, on resistive layer 8'. However, when provided, insulating layer 7 is then present not only between the anode strips, but also between the different elementary patterns of definition of reflective layer areas 10 and phosphor element areas 4. It should be noted that the fact that the additional conductive layer is deposited according to the elementary patterns enables keeping a floating potential at each pixel.

In the embodiment illustrated in Figs. 4A and 4B, resistive layer 8' is deposited without being patterned, that is, it extends over at least the entire active area of the anode.

An advantage of the second embodiment of the invention is that it particularly well applies to a transparent cathode screen. Indeed, by dissociating the reflective layer and resistive layer functions, a wider choice of materials is available to form the different layers. In particular, a resistive layer 8' made of an optically absorbing material (for example, silicon) can be provided. In this case, the resistive layer will then form a black matrix wherever there are no phosphor elements and no reflective layer 10. It will then absorb light, which improves the screen contrast.

Further, if the resistive layer is deposited without being patterned, and if it is made of a material with a small secondary emission coefficient (which is generally the case for resistive materials), it will protect the underlying layer between conductive layers 5B, 5R, and 5G that is generally made of a material with a very high secondary emission coefficient, and will then protect the anode against charge effects, which reduces the screen degassing.

As in the first embodiment, an advantage linked to the suppressing of the resistors at the ends of the anode conductive strips is, on the one hand, that space is gained on the anode, but also that the thermal effects due to the presence of these resistors are distributed throughout the entire anode plate. Localized heating, which risks being prejudicial, is thus avoided.

Figs. 5A and 5B show, respectively in front view and in cross-section, an alternative implementation of an anode according to the second embodiment of the invention. According to this alternative, resistive layer 8'' is itself deposited according to the elementary patterns of deposition of phosphor elements 4'. For clarity, the alignment differences between the elementary patterns of phosphor elements 4', of additional conductive layer

10, and of resistive layer 8" have been exaggerated in Figs. 5A and 5B. It should however be noted that these different elementary patterns are obtained by means of a same mask. Thus, the present invention remains compatible with conventional anode  
 5 manufacturing methods and, in particular, requires no additional mask, whatever the embodiment used.

In the alternative of Figs. 5A and 5B, conductive biasing strips 5B, 5R, and 5G have still been shown in strips as in the first embodiment.

10 It should be noted that, as an alternative, the resistive layer provided in the second embodiment of the present invention may also be deposited according to the pattern of biasing conductive strips 5B, 5R, and 5G. In this case, the advantage of using no additional mask for the deposition of this  
 15 resistive layer remains, as in the first embodiment.

In Fig. 5B, a resistive layer 8" relatively thicker than that illustrated in Fig. 4B has been shown. Indeed, according to the invention and whatever the embodiment, the value of the resistance can be adjusted according, for a given material,  
 20 to the thickness of the deposited resistive layer.

Of course, the present invention is likely to have various alterations, modifications, and improvements which will readily occur to those skilled in the art. In particular, It should be noted that, in the case of a monochrome screen or of an  
 25 unswitched anode screen, and as an application of the second embodiment of the present invention, biasing conductive layer 5 and resistive layer 8 may be deposited without being patterned. Reflective conductive layer 10 and the phosphor elements will then be deposited according to the elementary patterns of the  
 30 screen pixels. Further, the choice of materials to form a flat screen anode according to the invention is within the abilities of those skilled in the art based on the functional indications given hereabove and on the applications. It should further be noted that those skilled in the art will easily adapt the  
 35 thicknesses of the different layers and in particular of the

resistive layer according to the expected electric characteristics. Moreover, in the case of an unswitched anode, it should be noted that only the strips (or islands) of phosphor elements need individualizing in the active screen surface. Thus, biasing layer

5 5 may be a conductive plane and the resistive layer may not be patterned. There then is a single anode biasing electrode.

CLAIMS

1. A flat display screen anode, including phosphor elements (4R, 4G, 4B; 4'R, 4'G, 4'B) intended for being excited by an electron bombardment, these elements being deposited on at least one biasing electrode including, at least under the  
 5 phosphor elements, a resistive layer (8, 8', 8") deposited on a conductive layer (5B, 5R, 5G) for biasing the phosphor elements.

2. The anode of claim 1, wherein the phosphor elements (4B, 4R, 4G) are directly deposited on the resistive layer (8).

10 3. The anode of claim 1, wherein the phosphor elements (4'B, 4'G, 4'R) are deposited on a reflective conductive layer (10), itself deposited on the resistive layer (8', 8").

4. The anode of claim 3, wherein the reflective layer (10) is deposited according to elementary patterns of small  
 15 dimension in the anode surface.

5. The anode of claim 4, wherein the phosphor elements (4'B, 4'R, 4'G) are deposited according to the elementary pattern of deposition of the reflective layer (10).

6. The anode of any of claims 1 to 5, wherein the  
 20 resistive layer (8, 8', 8") is not patterned.

7. The anode of any of claims 3 to 5, wherein the resistive layer (8") has the same pattern as the reflective layer (10).

8. The anode of any of claims 1 to 7, wherein the  
 25 resistive layer (8) has, at least in the active screen area, the same pattern as the biasing conductive layer (5).

9. The anode of any of claims 1 to 8, wherein said conductive layer has a pattern of alternate strips (5R, 5G, 5B) interconnected in at least two sets.

30 10. A flat display screen including a cathode (1) for generating electrons bombarding the cathodoluminescent anode (2) of claim 1.

## FLAT DISPLAY SCREEN RESISTIVE ANODE

### Abstract

A flat display screen anode, including phosphor elements intended for being excited by an electron bombarding, these elements being deposited on at least one biasing electrode including, at least under the phosphor elements, a resistive layer deposited on a conductive layer for biasing the phosphor elements.

As a below named inventor, I hereby declare that:

My residence, post office address, and citizenship are as stated below next to my name.

I believe I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled:

**FLAT DISPLAY SCREEN RESISTIVE ANODE**

☒ the specification of which (Title of the Invention)

is attached hereto

OR

☐ was filed on (MM/DD/YYYY) [ ] as United States Application Number or PCT International

Application Number [ ] and was amended on (MM/DD/YYYY) [ ] (if applicable).

I hereby state that I have reviewed and understand the contents of the above identified specification, including the claims, as amended by any amendment specifically referred to above.

I acknowledge the duty to disclose information which is material to patentability as defined in 37 CFR 1.56.

I hereby claim foreign priority benefits under 35 U.S.C. 119(a)-(d) or 365(b) of any foreign application(s) for patent or inventor's certificate, or 365(a) of any PCT international application which designated at least one country other than the United States of America, listed below and have also identified below, by checking the box, any foreign application for patent or inventor's certificate, or of any PCT international application having a filing date before that of the application on which priority is claimed.

## DECLARATION — Utility or Design Patent Application

I hereby claim the benefit under 35 U.S.C. 120 of any United States application(s), or 35(c) of any PCT international application designating the United States of America, listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States or PCT international application in the manner provided by the first paragraph of 35 U.S.C. 112, I acknowledge the duty to disclose information which is material to patentability as defined in 37 CFR 1.56 which became available between the filing date of the prior application and the national or PCT international filing date of this application.

U.S. Parent Application or PCT Parent Number	Parent Filing Date (MM/DD/YYYY)	Parent Patent Number (if applicable)

☐ Additional U.S. or PCT international application numbers are listed on a supplemental priority data sheet PTO/SB/02B attached hereto.

As a named inventor, I hereby appoint the following registered practitioner(s) to prosecute this application and to transact all business in the Patent and Trademark Office connected therewith: ☐ Customer Number  OR ☒ Registered practitioner(s) name/registration number listed below
